The larger the sample size, the more precise the mean. For instance, if you find that, among 40 people, the mean height is 5 feet, 4 inches, but among 100 people, the mean height is 5 feet, 3 inches, the second measurement is a better estimation of the average height of an individual, since you're testing substantially more subjects.

At the end of the course students will understand how to use power analysis to effectively plan the appropriate sample size for a study. They will learn to recognize which factors are controllable and which are not, and how to balance those factors to find the optimal trade-off between feasible sample size and acceptable power.

Sample size depends on population size but not in an expected way. First of all, it doesn't increase. The sample size doesn't increase as the population size does. And above a certain limit of population size basically it's the same, it's unaffected. If anything, if we get the small population sizes, that sample size drops.
